#### Overview

#### Recall module is roughly split into four parts:

- 1. Random events: counting, events, axioms of probability, Bayes, independence
- Random variables: discrete RVs, mean and variance, correlation, conditional expectation Mid-term
- 3. <u>Inequalities and laws of large numbers</u>: Markov, Chebyshev, sample mean, weak law of large numbers, central limit theorem, confidence intervals, bootstrapping
- 4. <u>Statistical models:</u> continuous random variables, logistic regression, least squares

#### Overview

- Markov's Inequality
- Chebyshev's Inequality

#### Why Are Inequalities Useful?

We may not know the true form of a probability distribution

#### Opinion polls

The 2016 General Election Exit Poll was conducted exclusively on behalf of The Irish Times by Ipsos MRBI, among a national sample of 5,260 voters at 200 polling stations throughout all constituencies in the Republic of Ireland.

Voters were randomly selected to self-complete a mock ballot paper on exiting the polling station. The accuracy level is estimated to be approximately plus or minus 1.2 per cent.

- Stock market data
- Weather tomorrow

But we may know some of its properties

- Mean
- Variance
- Non-negativity

Inequalities let us say something about the probability distribution in such cases, although often imprecise. They are also  $\nu$  important for looking at what happens as we collect more and more measurements ("law of large numbers").

Often we want to know:

What is the probability that the value of r.v. X is "far" from its mean?

A generic answer for non-negative X is Markov's inequality. Say X is a non-negative random variable. Then:

$$P(X \ge a) \le \frac{E(X)}{a}$$
 for all  $a > 0$ 

Proof:

- Let indicator  $I_a(X)=1$  if  $X\geq a$  and  $I_a(X)=0$  otherwise. Then  $aI_a(X)\leq X$  i.e.  $I_a(X)\leq \frac{X}{a}$ .
- $E(I_a(X)) \leq E(\frac{X}{a}) = \frac{E(X)}{a}$
- $E(I_a(X)) = P(X \ge a) \le \frac{E(X)}{a}$

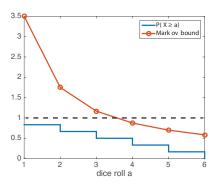

Andrey Andreyevich Markov (1856-1922) was a Russian mathematician

- Markov's inequality is named after him
- Also Markov Chains, used e.g. in Google's PageRank algorithm

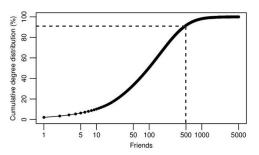

Example: Roll 6-sided dice.

- Mean is  $E[X] = 1 \times \frac{1}{6} + 2 \times \frac{1}{6} + \dots + 6 \times \frac{1}{6} = 3.5$
- Markov inequality:  $P(X \ge 5) \le \frac{3.5}{5} = 0.7$ . Exact:  $P(X = 5) + P(X = 6) = \frac{1}{6} + \frac{1}{6} = 0.33$
- So a loose bound, but it made <u>no</u> assumptions about the form of distribution.

Example: Distribution of number X of facebook friends.

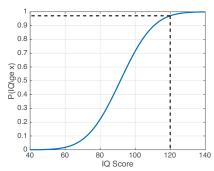

- Mean is E(X) = 190 (!)
- Markov inequality:  $P(X \ge 500) \le \frac{190}{500} = 0.38$ . From plot,  $P(X \ge 500) \approx 0.1$ .
- Markov inequality:  $P(X \ge 190) \le \frac{190}{190} = 1$ , non-informative. From plot,  $P(X \ge 190) \approx 0.3$ .

source: http://arxiv.org/abs/1111.4503

Example: IQ in Ireland

- Mean is E(X) = 92. Score 110-119 = "high average", 120-129 = "superior".
- Markov inequality:  $P(X \ge 110) \le \frac{92}{110} = 0.83$ . From data,  $P(X \ge 110) \approx 0.11$ .
- Markov inequality:  $P(X \ge 120) \le \frac{92}{120} = 0.76$ . From data,  $P(X \ge 120) \approx 0.029$ .

Suppose X is a random variable with mean  $E(X) = \mu$  and variance  $var(X) = \sigma^2$ . Then

$$P(|X - \mu| \ge k) \le \frac{\sigma^2}{k^2}$$
 for all  $k > 0$ 

Proof:

• Since  $(X - \mu)^2$  is a non-negative random variable we can apply Markov's inequality with  $a = k^2$  to get

$$P((X - \mu)^2 \ge k^2) \le \frac{E((X - \mu)^2)}{k^2} = \frac{\sigma^2}{k^2}$$

• Note that  $(X - \mu)^2 \ge k^2 \iff |X - \mu| \ge k$ , so

$$P(|X - \mu| \ge k) \le \frac{\sigma^2}{k^2}$$

Pafnuty Lvovich Chebyshev (1821 - 1894) also a Russian mathematician

- Chebyshev's inequality was in fact first formulated by French mathematician Jules Bienaymé without proof, then proved by Chebyshev 14 years later.
- Markov was a graduate student of Chebyshev (also Aleksandr Lyapunov, but that's another days work)

Chebyshev's inequality links the "spread" of values of a random variable around its mean to the variance  $\sigma^2$ :

• Applying Chebyshev's inequality  $P(|X - \mu| \ge k) \le \frac{\sigma^2}{k^2}$  with  $k = n\sigma$  gives:

$$P(|X-\mu| \ge n\sigma) \le \frac{1}{n^2}$$

- With n = 3 then  $P(|X \mu| \ge 3\sigma) \le \frac{1}{9} = 0.11$ .
- This holds even when distribution is not Gaussian, so can be quite handy (if conservative).

Example: Roll 6-sided dice.

- Mean is  $E[X] = 1 \times \frac{1}{6} + 2 \times \frac{1}{6} + \dots + 6 \times \frac{1}{6} = 3.5$
- Variance is  $Var(X) = E[X^2] E[X]^2$ .  $E[X^2] = 1^2 \times \frac{1}{6} + 2^2 \times \frac{1}{6} + \dots + 6^2 \times \frac{1}{6} \approx 15.17$ ,  $Var(X) = 15.17 - 3.5^2 \approx 2.9$
- Chebyshev inequality:  $P(|X 3.5| \ge 2.5) \le \frac{2.9}{2.5^2} = 0.46$ .
- Exact:  $P(|X 3.5| \ge 2.5) = P(X = 1) + P(X = 6) = \frac{1}{6} + \frac{1}{6} = 0.33$
- A loose bound, but use of variance in Chebyshev inequality can improve accuracy cf Markov inequality.

#### Example: IQ in Ireland

- Mean is E(X) = 92, variance is  $\sigma^2 = 225$ .
- Chebyshev inequality:  $P(|X 92| \ge 20) \le \frac{225}{400} = 0.56$ . From data,  $P(|X 92| \ge 20) \approx 0.18$ .
- Markov inequality:  $P(X \ge 112) \le \frac{92}{112} = 0.82$ . And need to add  $P(X \le 72)$  to this.
